 van de Voort+2018)

ISM MORPHOLOGY - AFFECTED BY GRAVITATIONAL POTENTIAL

ISM MORPHOLOGY - AFFECTED BY GRAVITATIONAL POTENTIAL

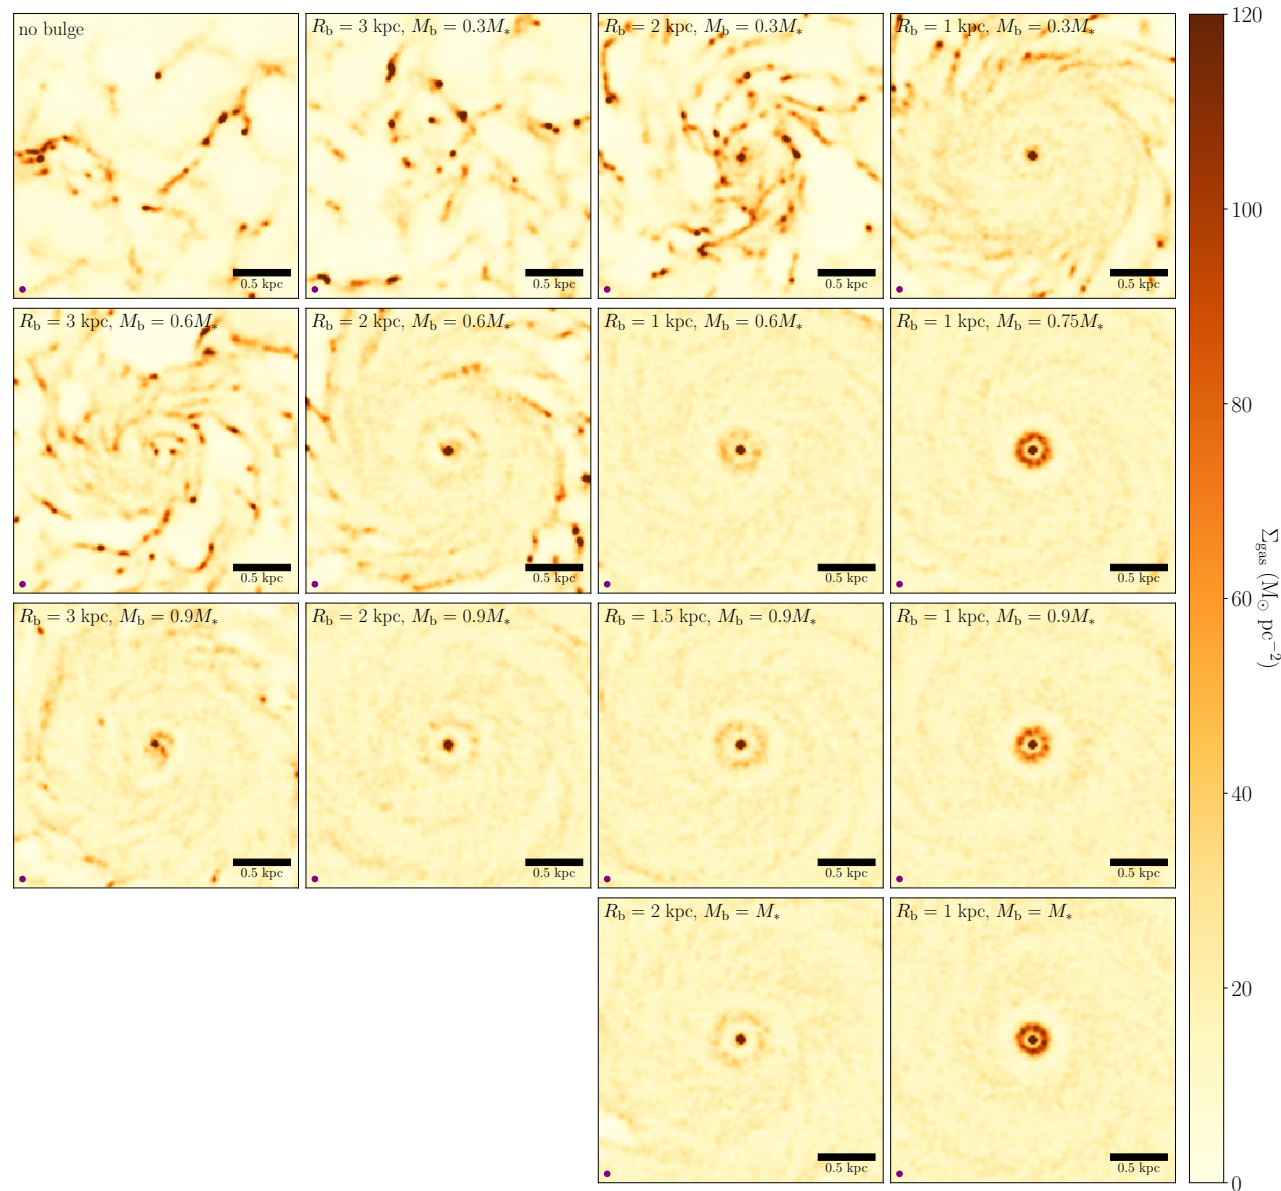

- WISDOM sample: high resolution ALMA CO observations (mainly $J=2 \rightarrow 1$, sometimes $J=3 \rightarrow 2$) of galaxy (centre)s
 - Original aim: dynamically measure SMBH masses (e.g. Onishi+2017, Davis+2017, 2018, 2020, North+2019, 2021, Smith+2019, 2021, Lelli+2021, Ruffa+2023, Liang+2024)
 - Wealth of GMC science possible (e.g. Liu+2021, 2022, Lu+2022, Choi+2023, Williams+2023)
- Galaxy morphologies ranging from LTGs to ETGs

SELECTION CRITERIA

- Inclination $< 65^\circ$
- Geometric beam average axis $< 100\text{pc}$

THE SAMPLE

Central regions of 14 simulated galaxies

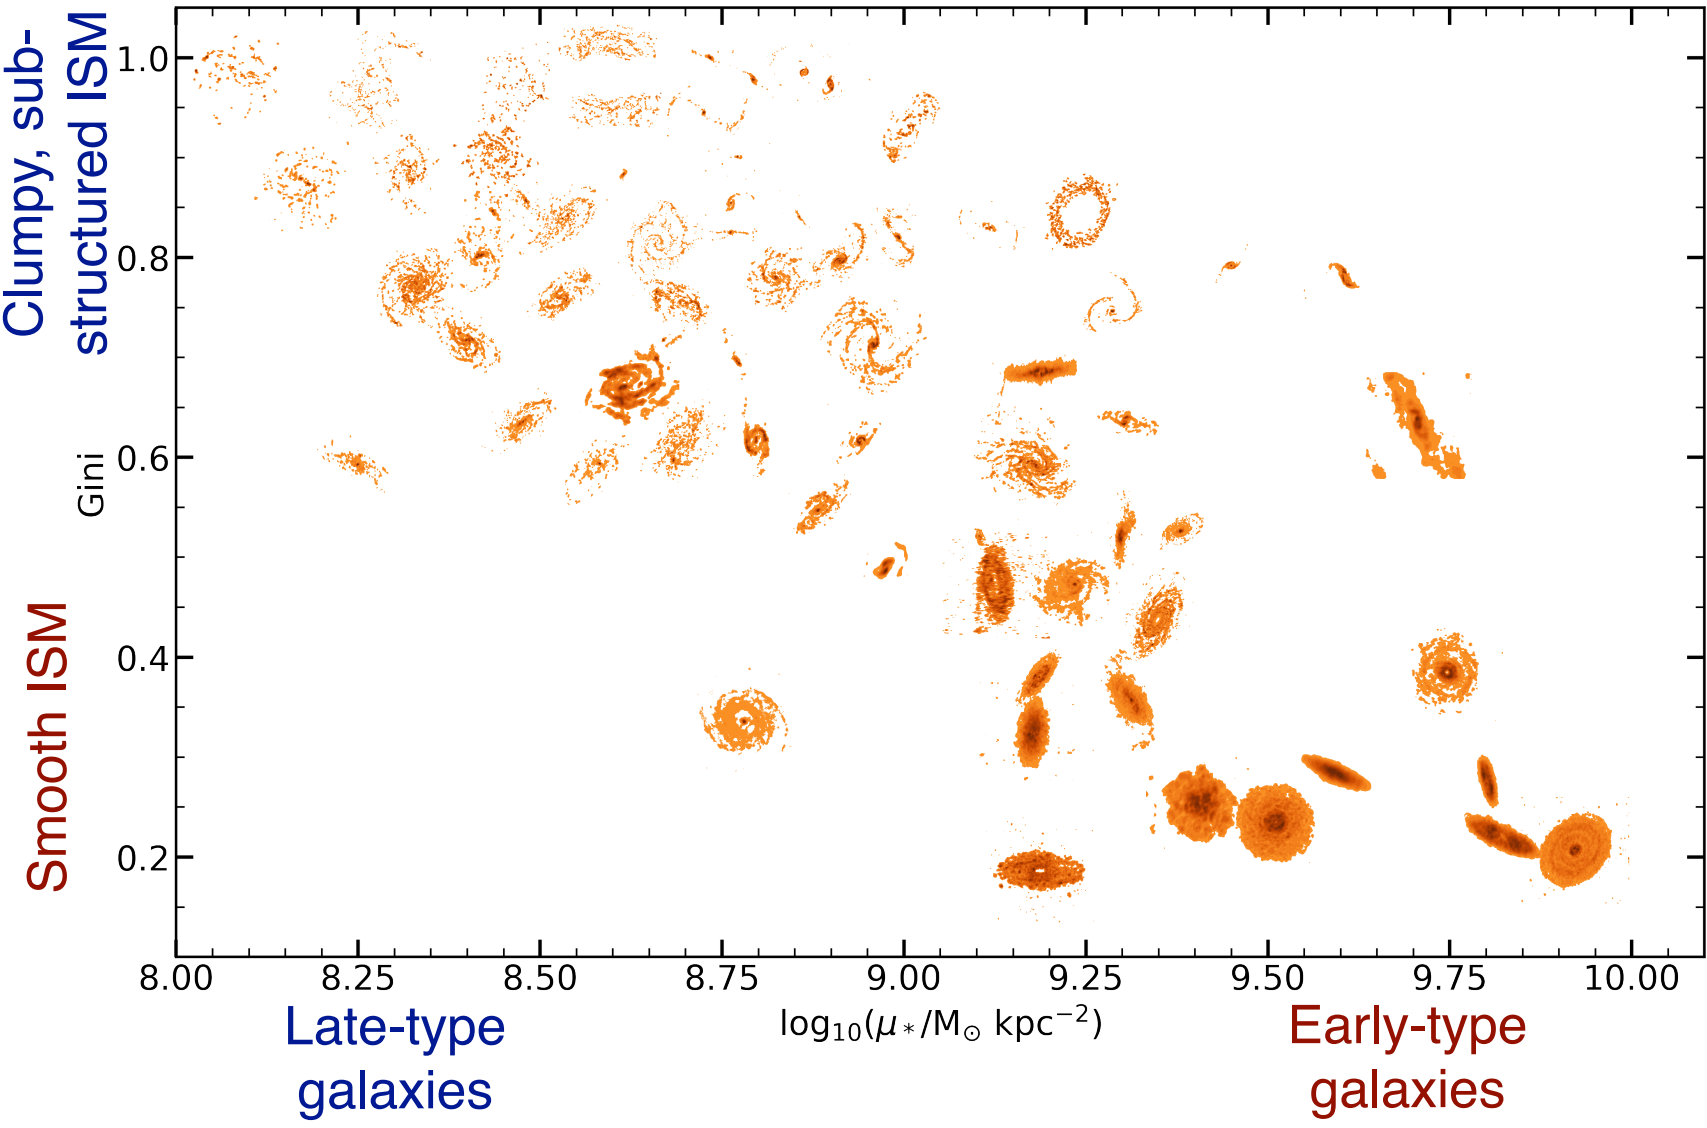

12 WISDOM galaxies

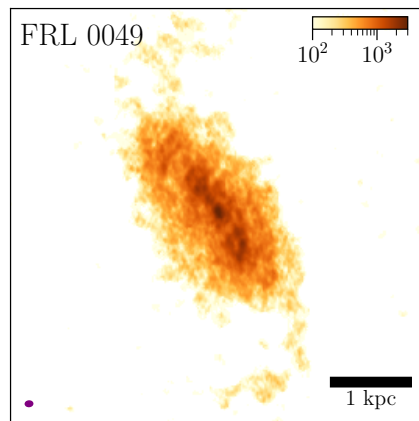

Use **TurbuStat** (Koch+ 2019) to obtain power spectra

QUANTIFYING ISM MORPHOLOGY WITH NON-PARAMETRIC INDICATORS

■ ISM morphology strongly correlated with μ_* (stellar potential)

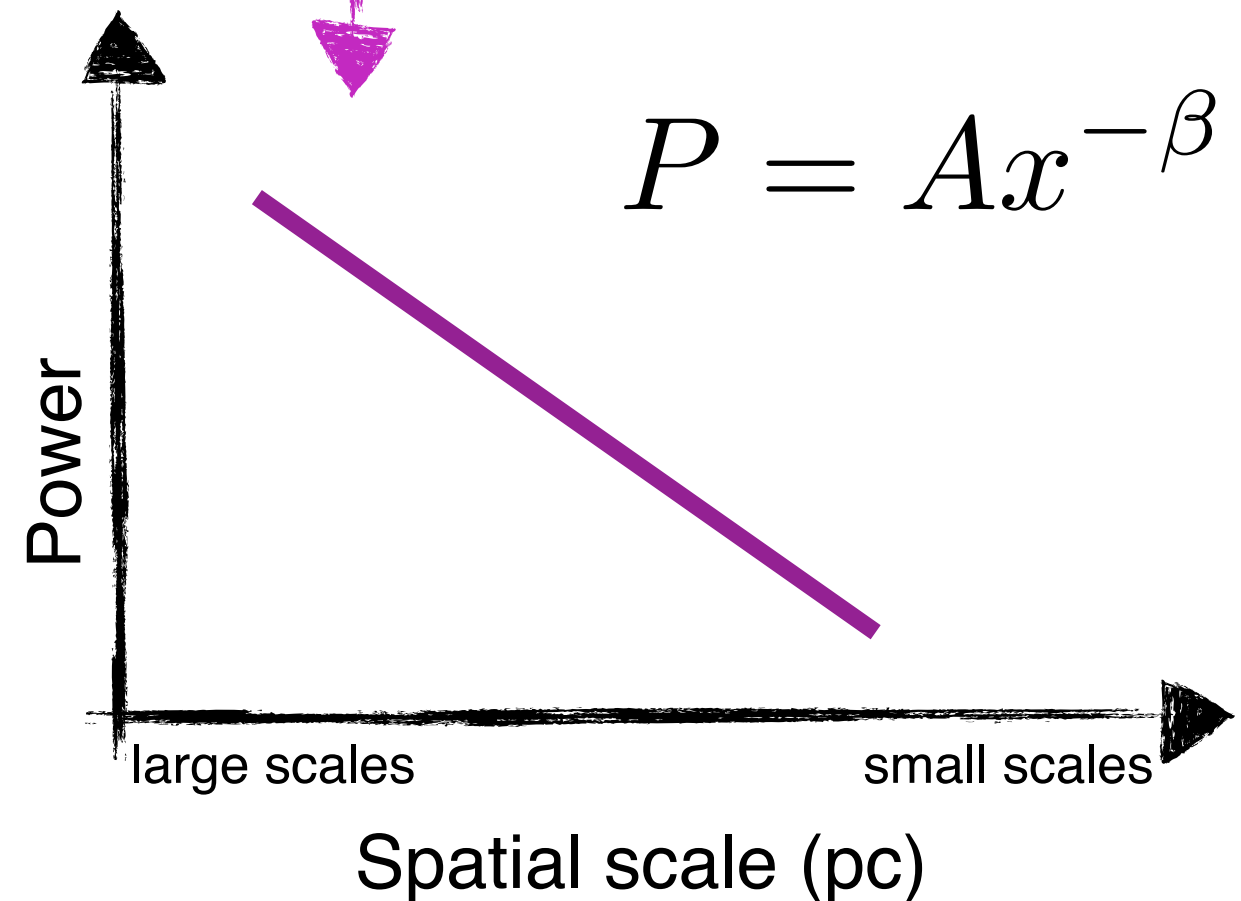

WHAT IS THE SPATIAL POWER SPECTRUM?

1. Fourier transform x complex conjugate

2. Azimuthal average

3. Fit power law

WHAT IS THE SPATIAL POWER SPECTRUM?

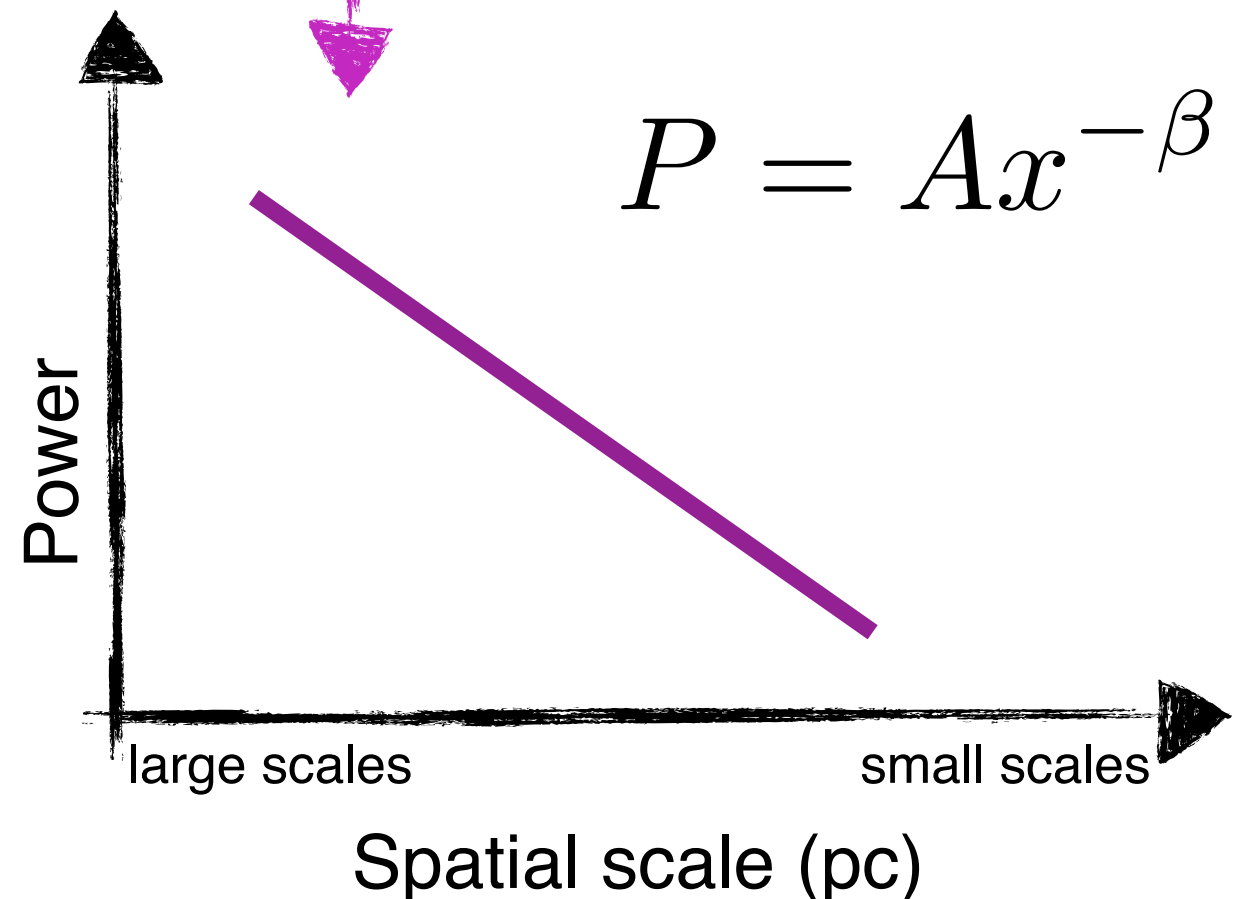

1. Fourier transform x complex conjugate

2. Azimuthal average

3. Fit power law

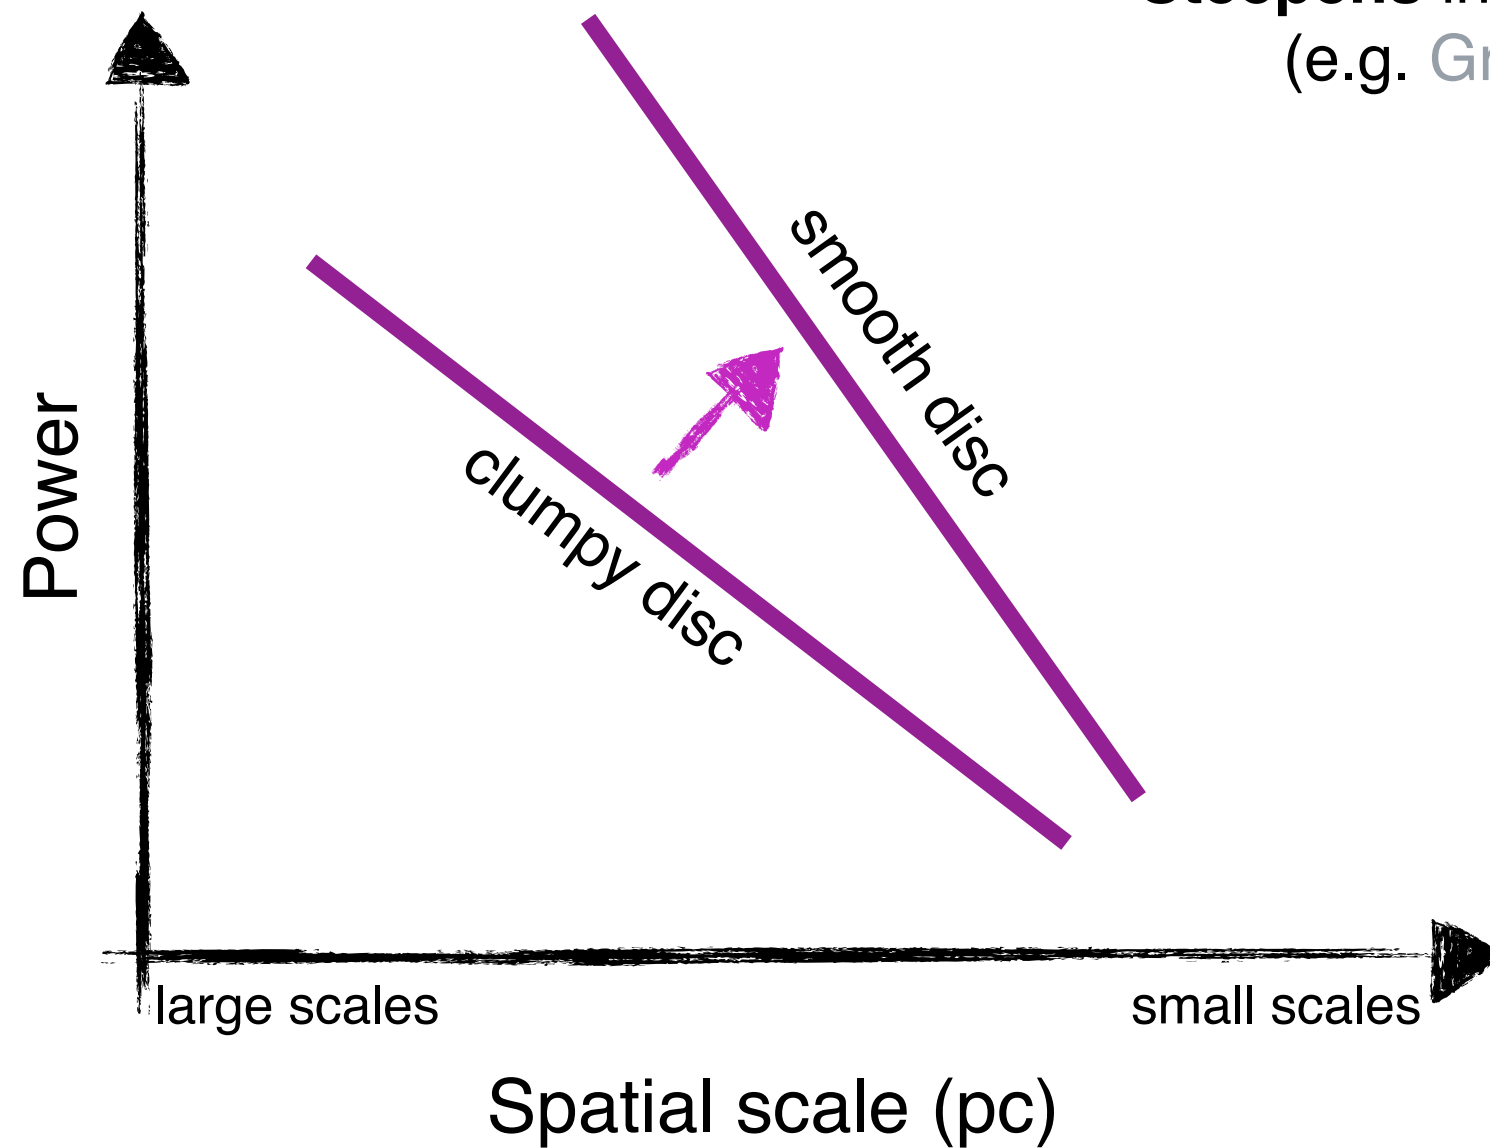

- Power spectrum index (β) expected to depend on nature of turbulence (e.g. Elmegreen & Scale 2004, Federrath+2013, Nandakumar & Dutta 2020)
- β sensitive to ISM morphology (e.g. Walker+2014, Grisdale+2017, Koch+2020)
 - Predominantly HI studied for HI observations of galaxies
- Has been used to highlight need for stellar feedback + validate feedback models (e.g. Walker+2014, Grisdale+2017)

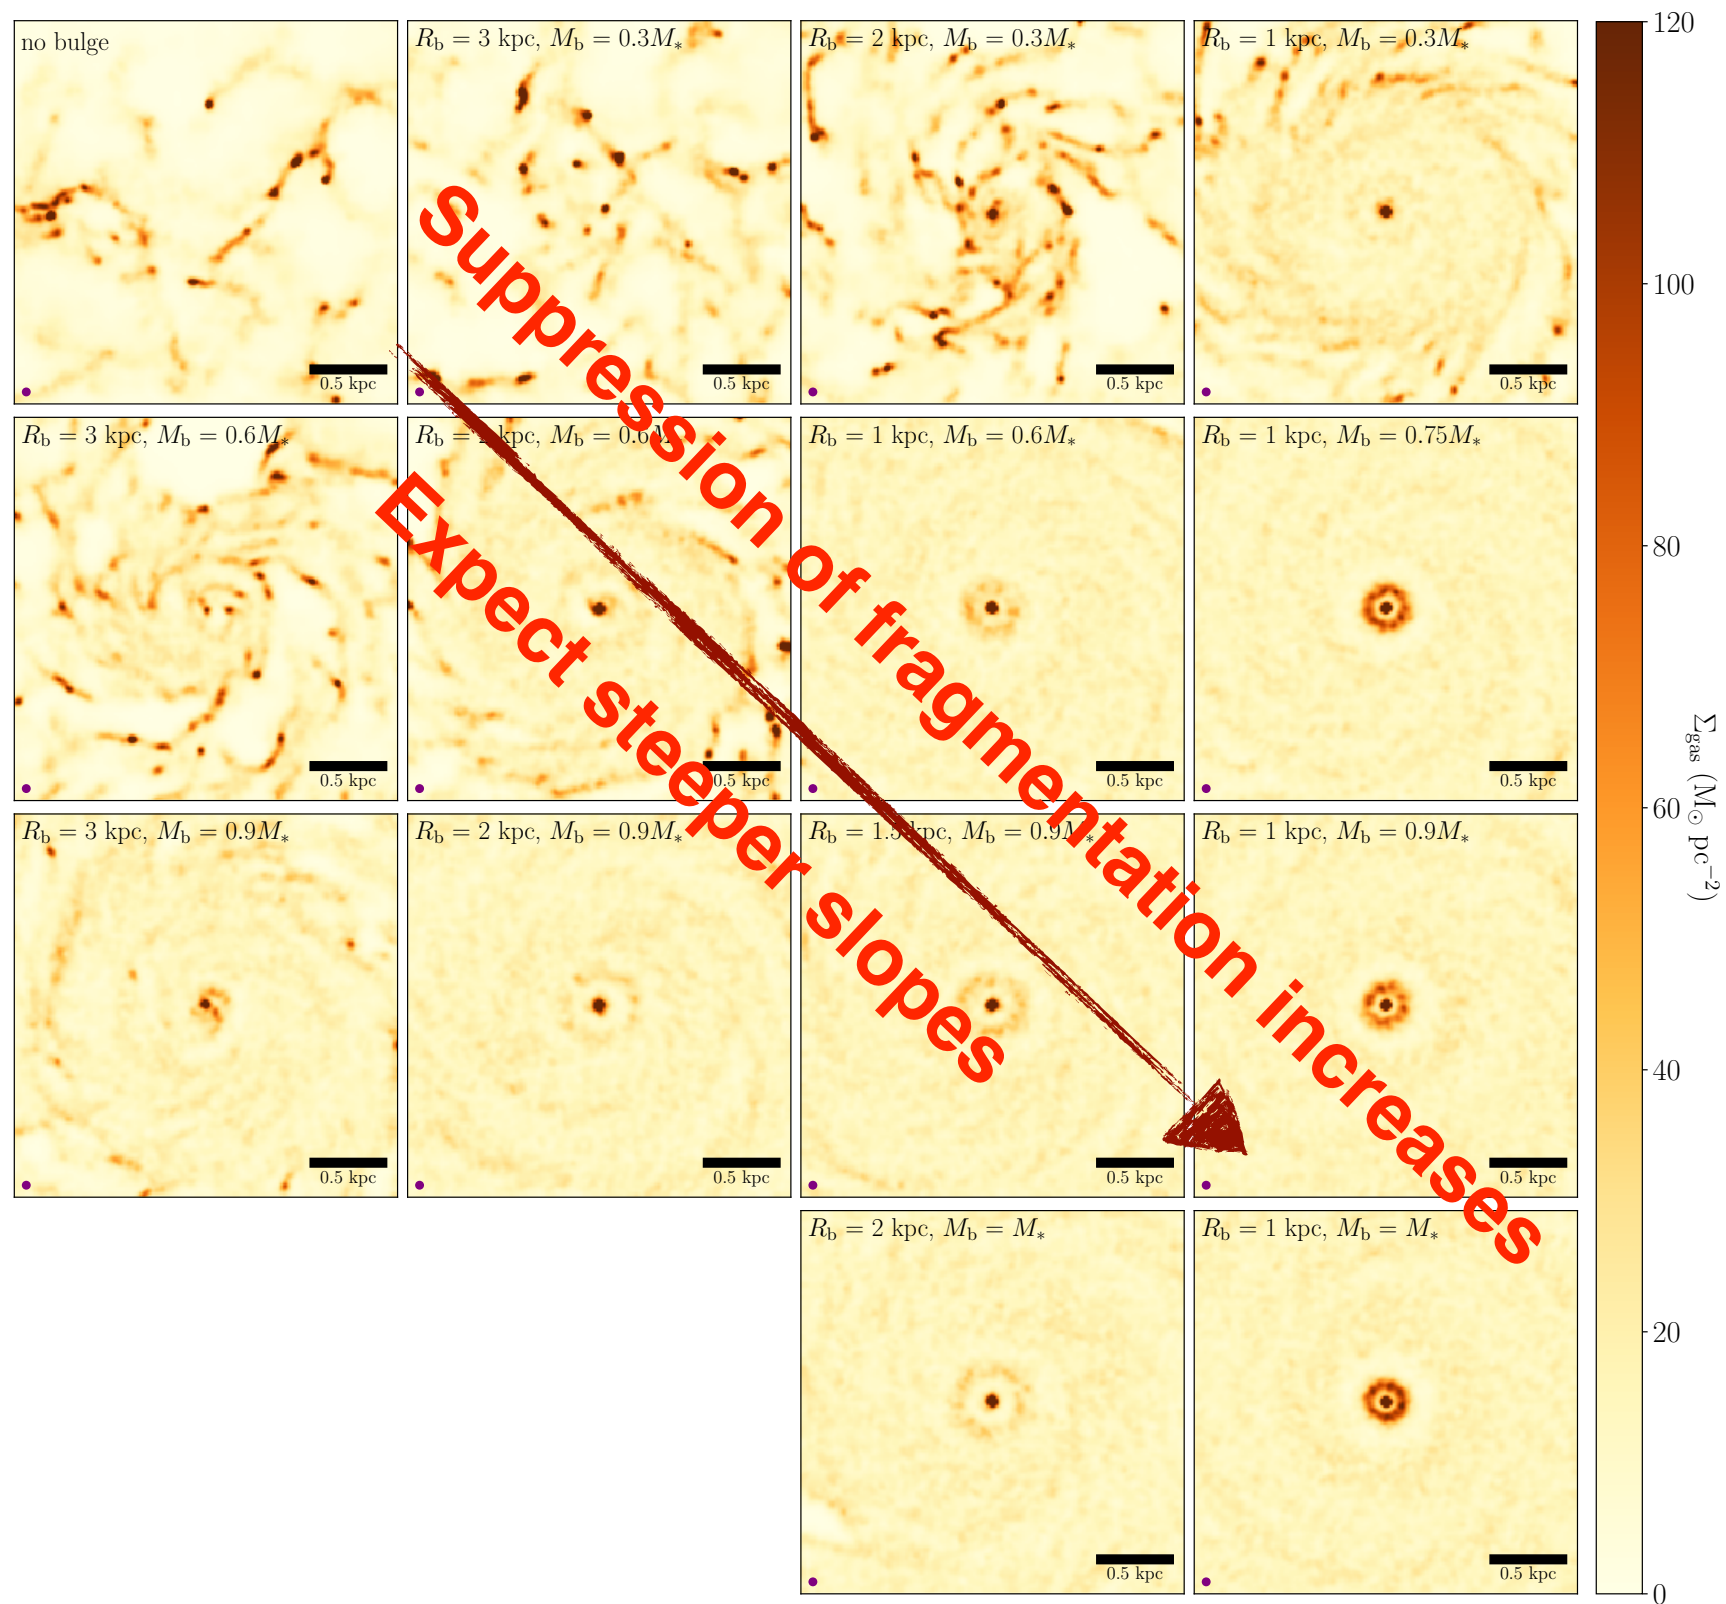

QUANTIFYING ISM MORPHOLOGY WITH THE DENSITY POWER SPECTRUM

$$P = Ax^{-\beta}$$

Steepens in absence of fragmentation
(e.g. Grisdale+17, Koch+20)

SIMULATIONS: EXPECTATIONS FOR POWER SPECTRUM SLOPES

SIMULATIONS: QUANTIFYING THE DYNAMICAL SUPPRESSION OF FRAGMENTATION

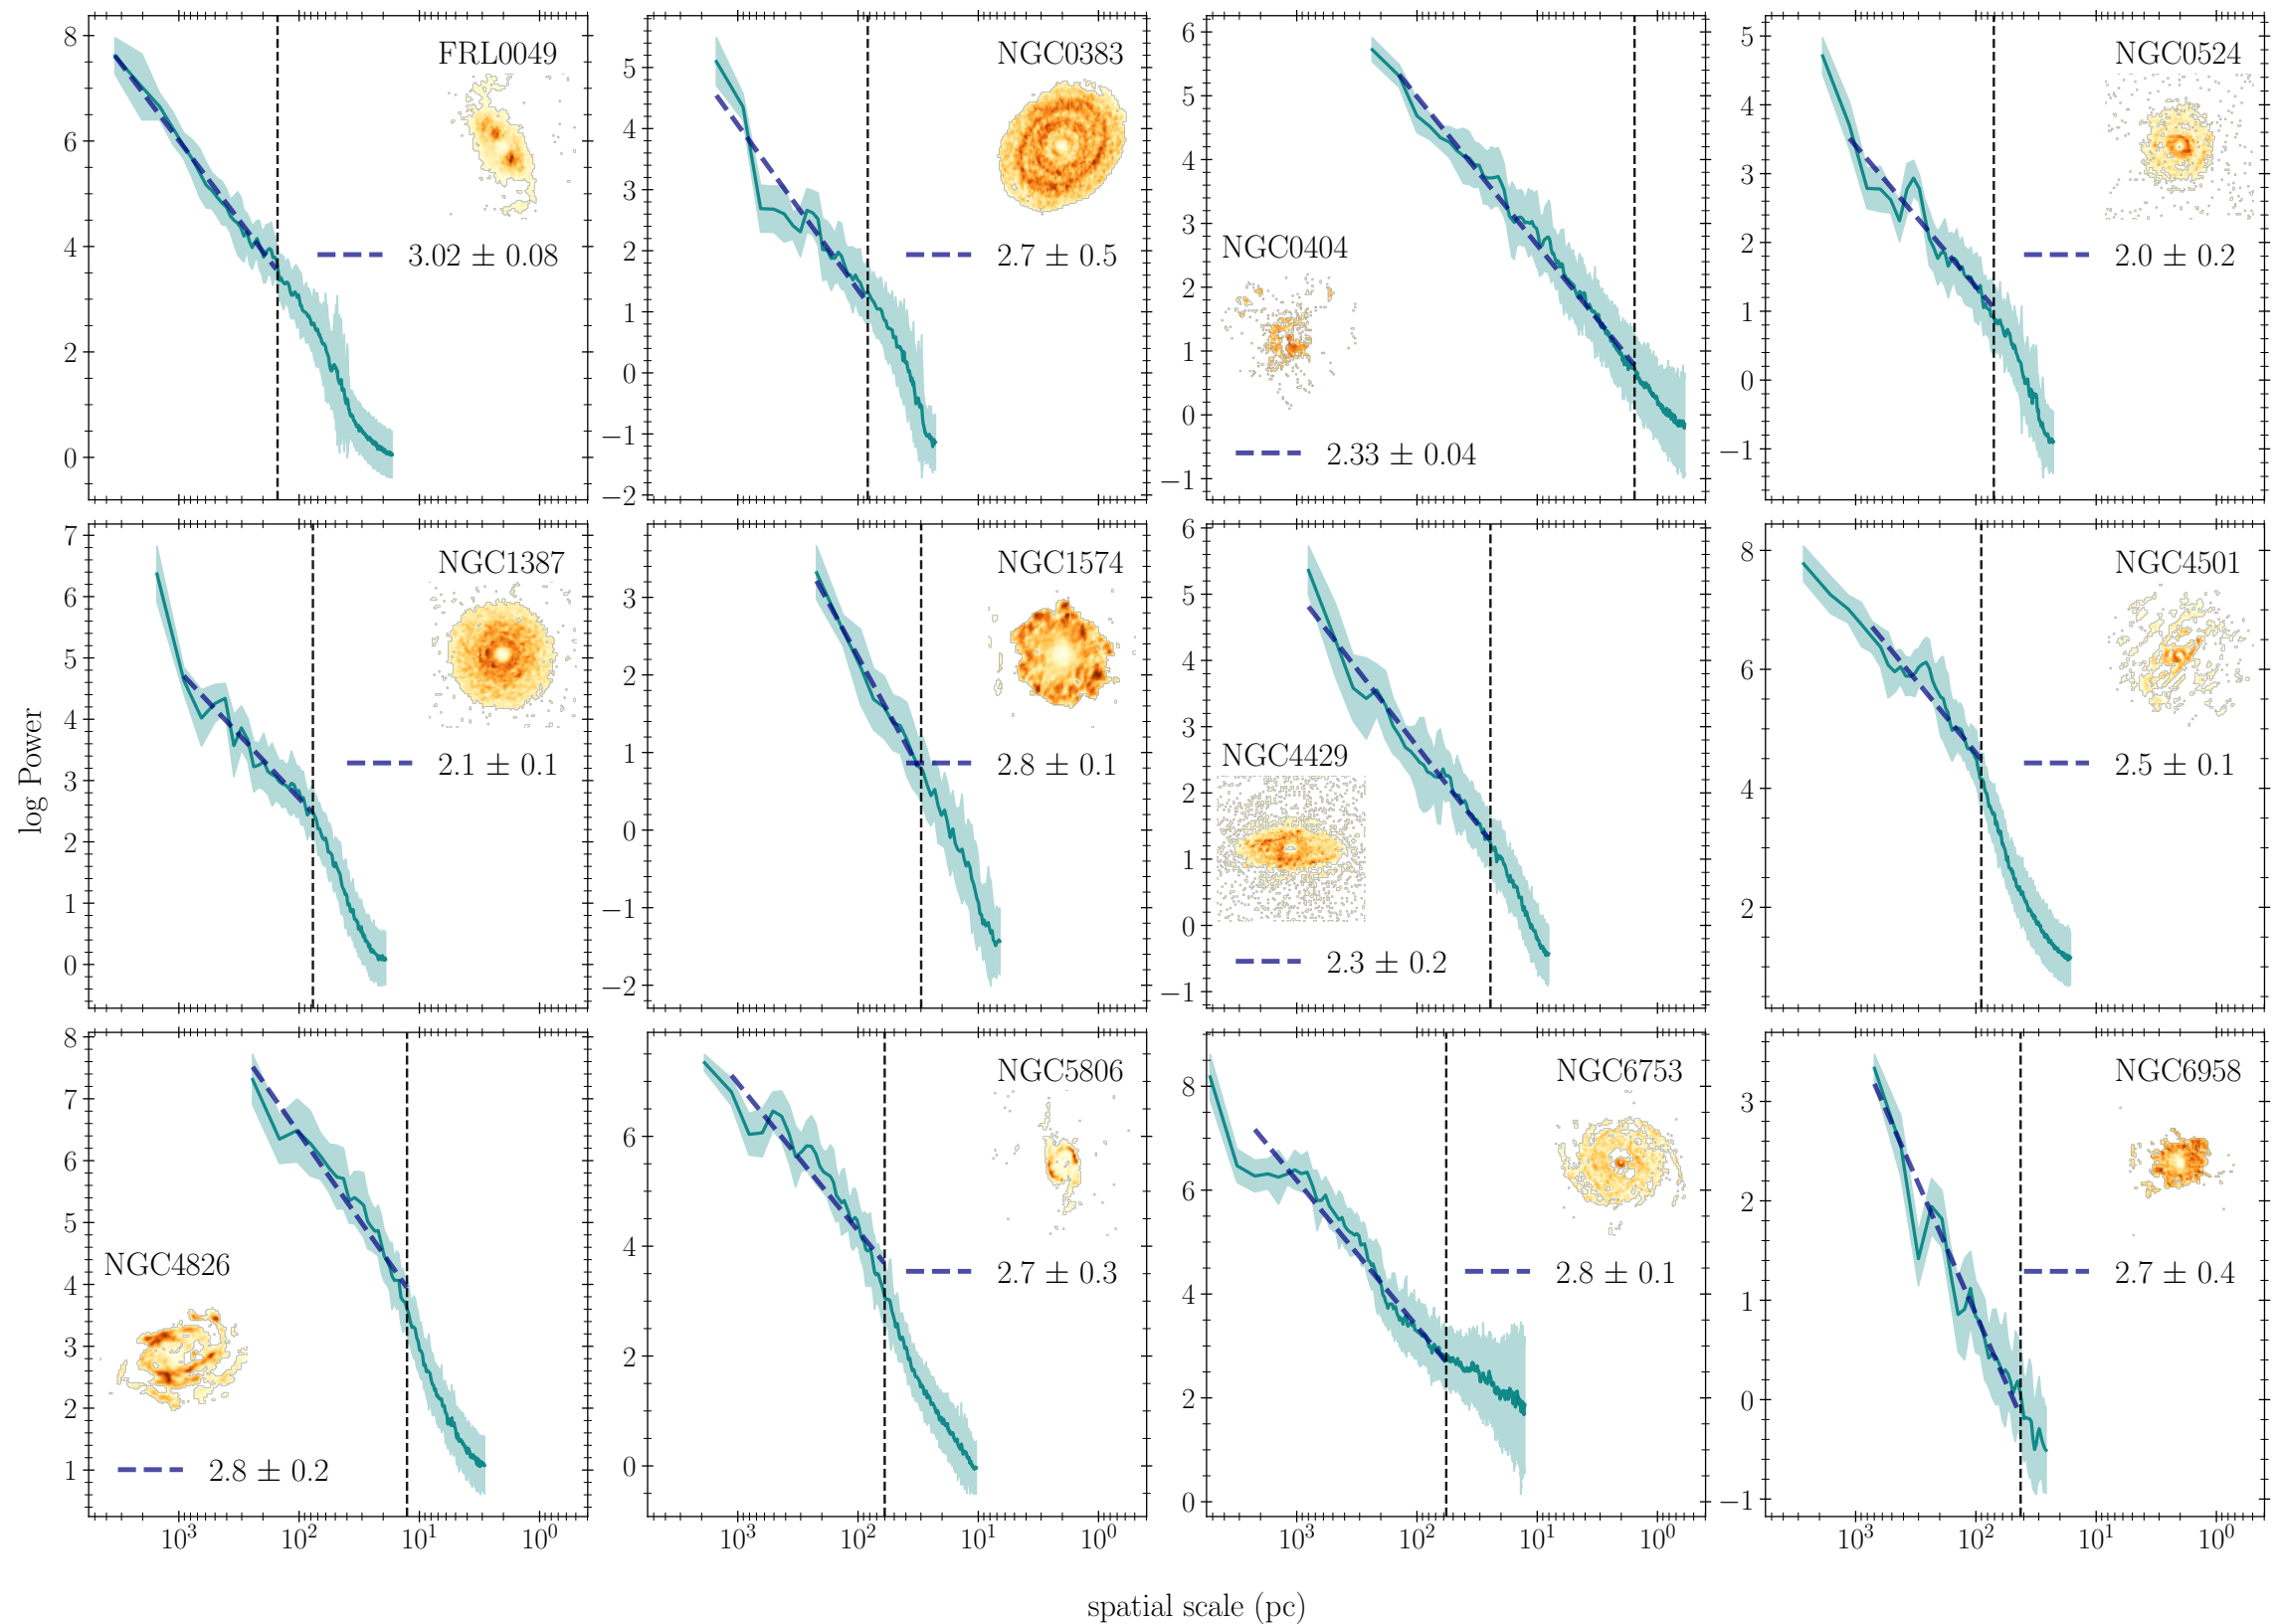

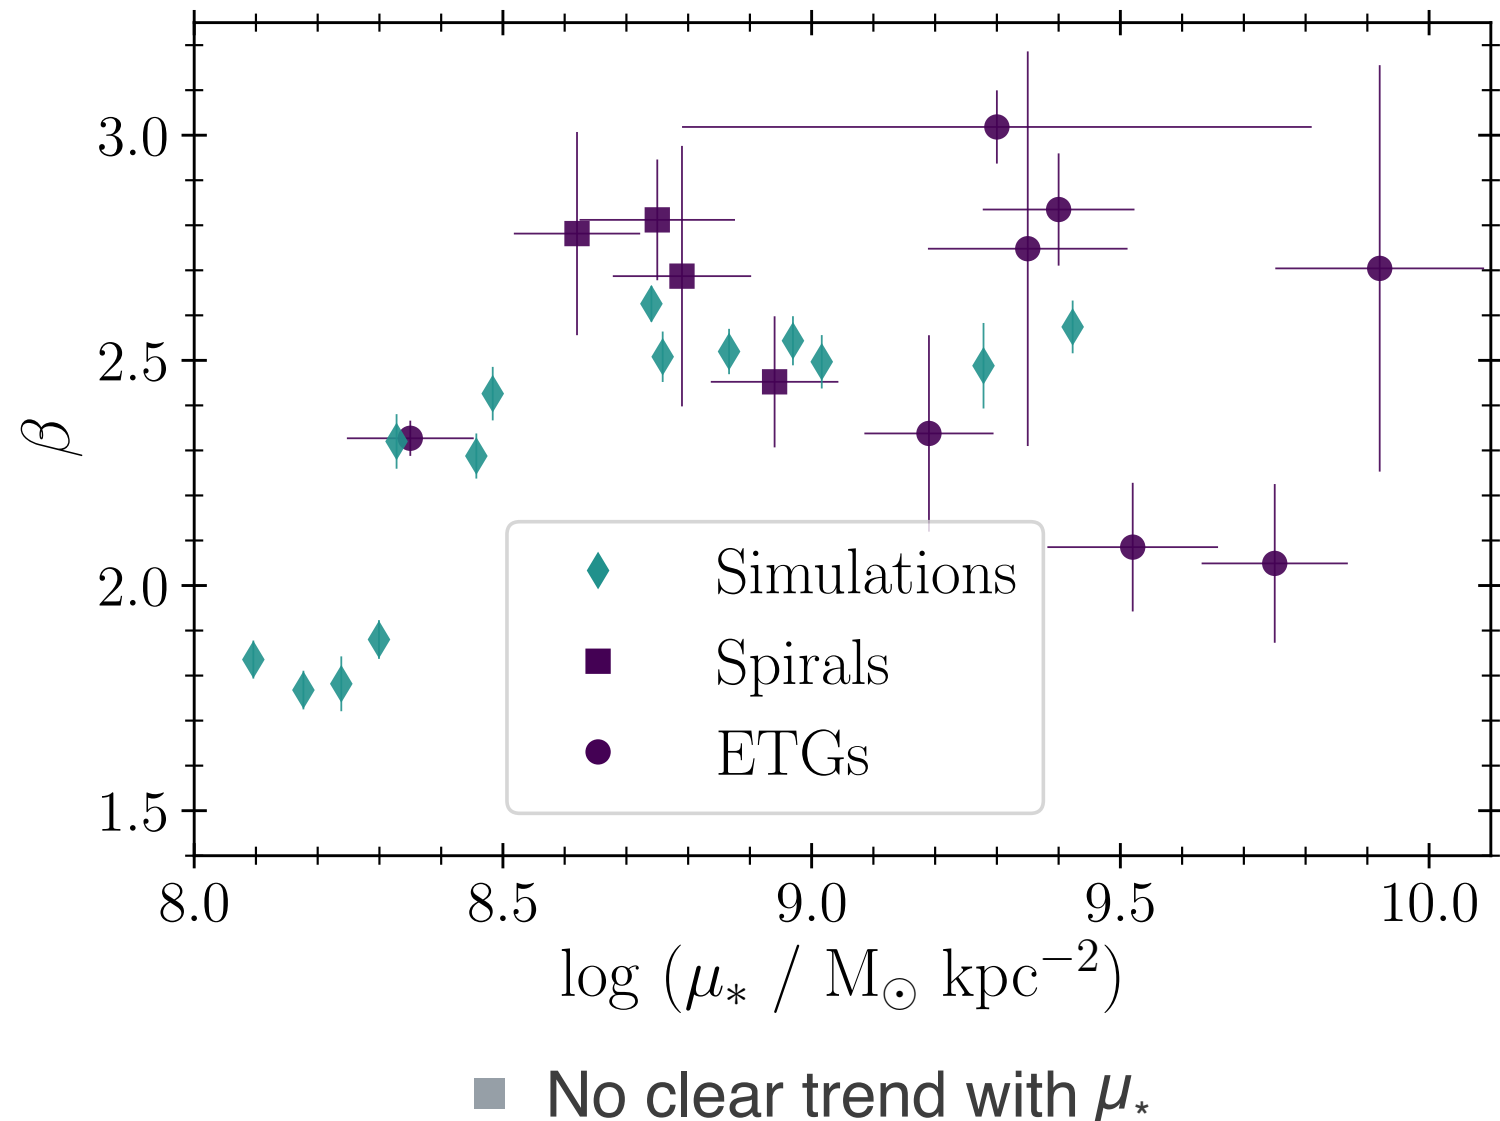

■ Steeper slopes with increasing μ_* (bulge strength)

➔ Dynamical suppression of fragmentation measurable with power spectrum

OBSERVATIONS: QUANTIFYING THE DYNAMICAL SUPPRESSION OF FRAGMENTATION

- ➔ WISDOM galaxies probably have more sources of turbulence cf. isolated galaxy simulations

- ➔ WISDOM galaxies probably have more sources of turbulence cf. isolated galaxy simulations
- ➔ Scatter around $\beta \sim 2.6-2.7$ could indicate incompressible turbulence driven by shear

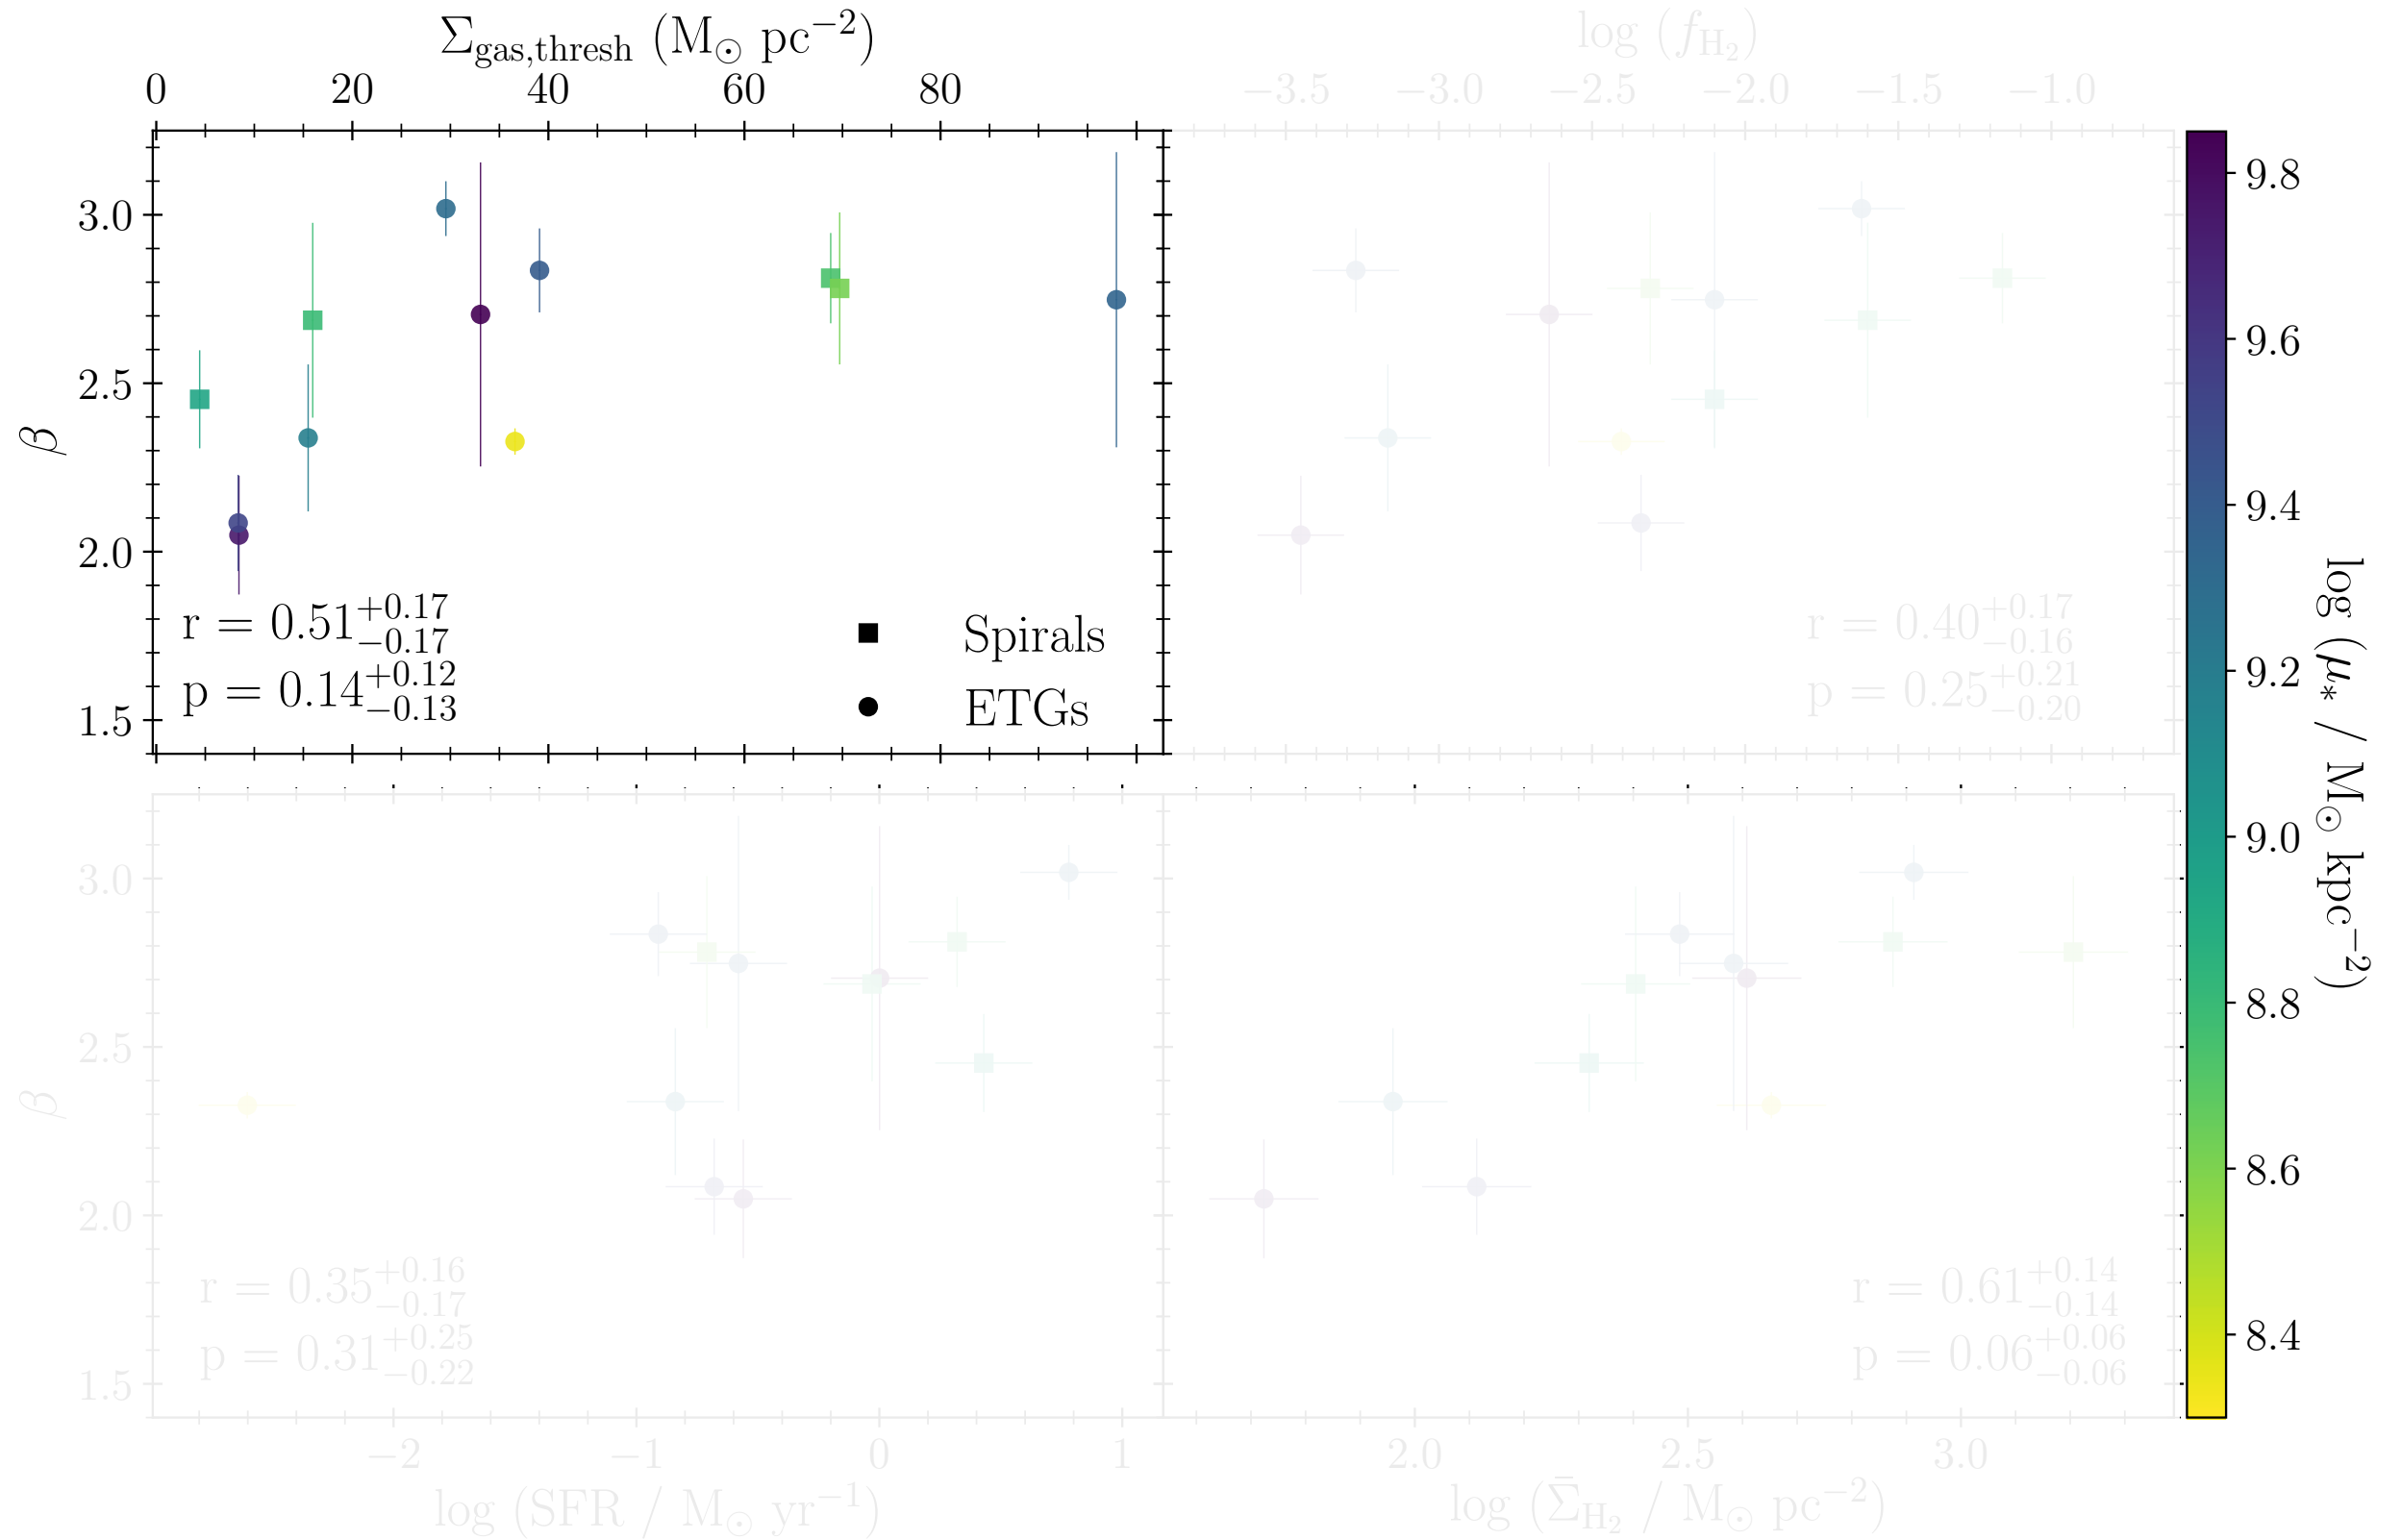

OBSERVATIONS:

POWER SPECTRUM SLOPE CORRELATES WITH CENTRAL GAS SURFACE DENSITY

OBSERVATIONS:

POWER SPECTRUM SLOPE CORRELATES WITH CENTRAL GAS SURFACE DENSITY

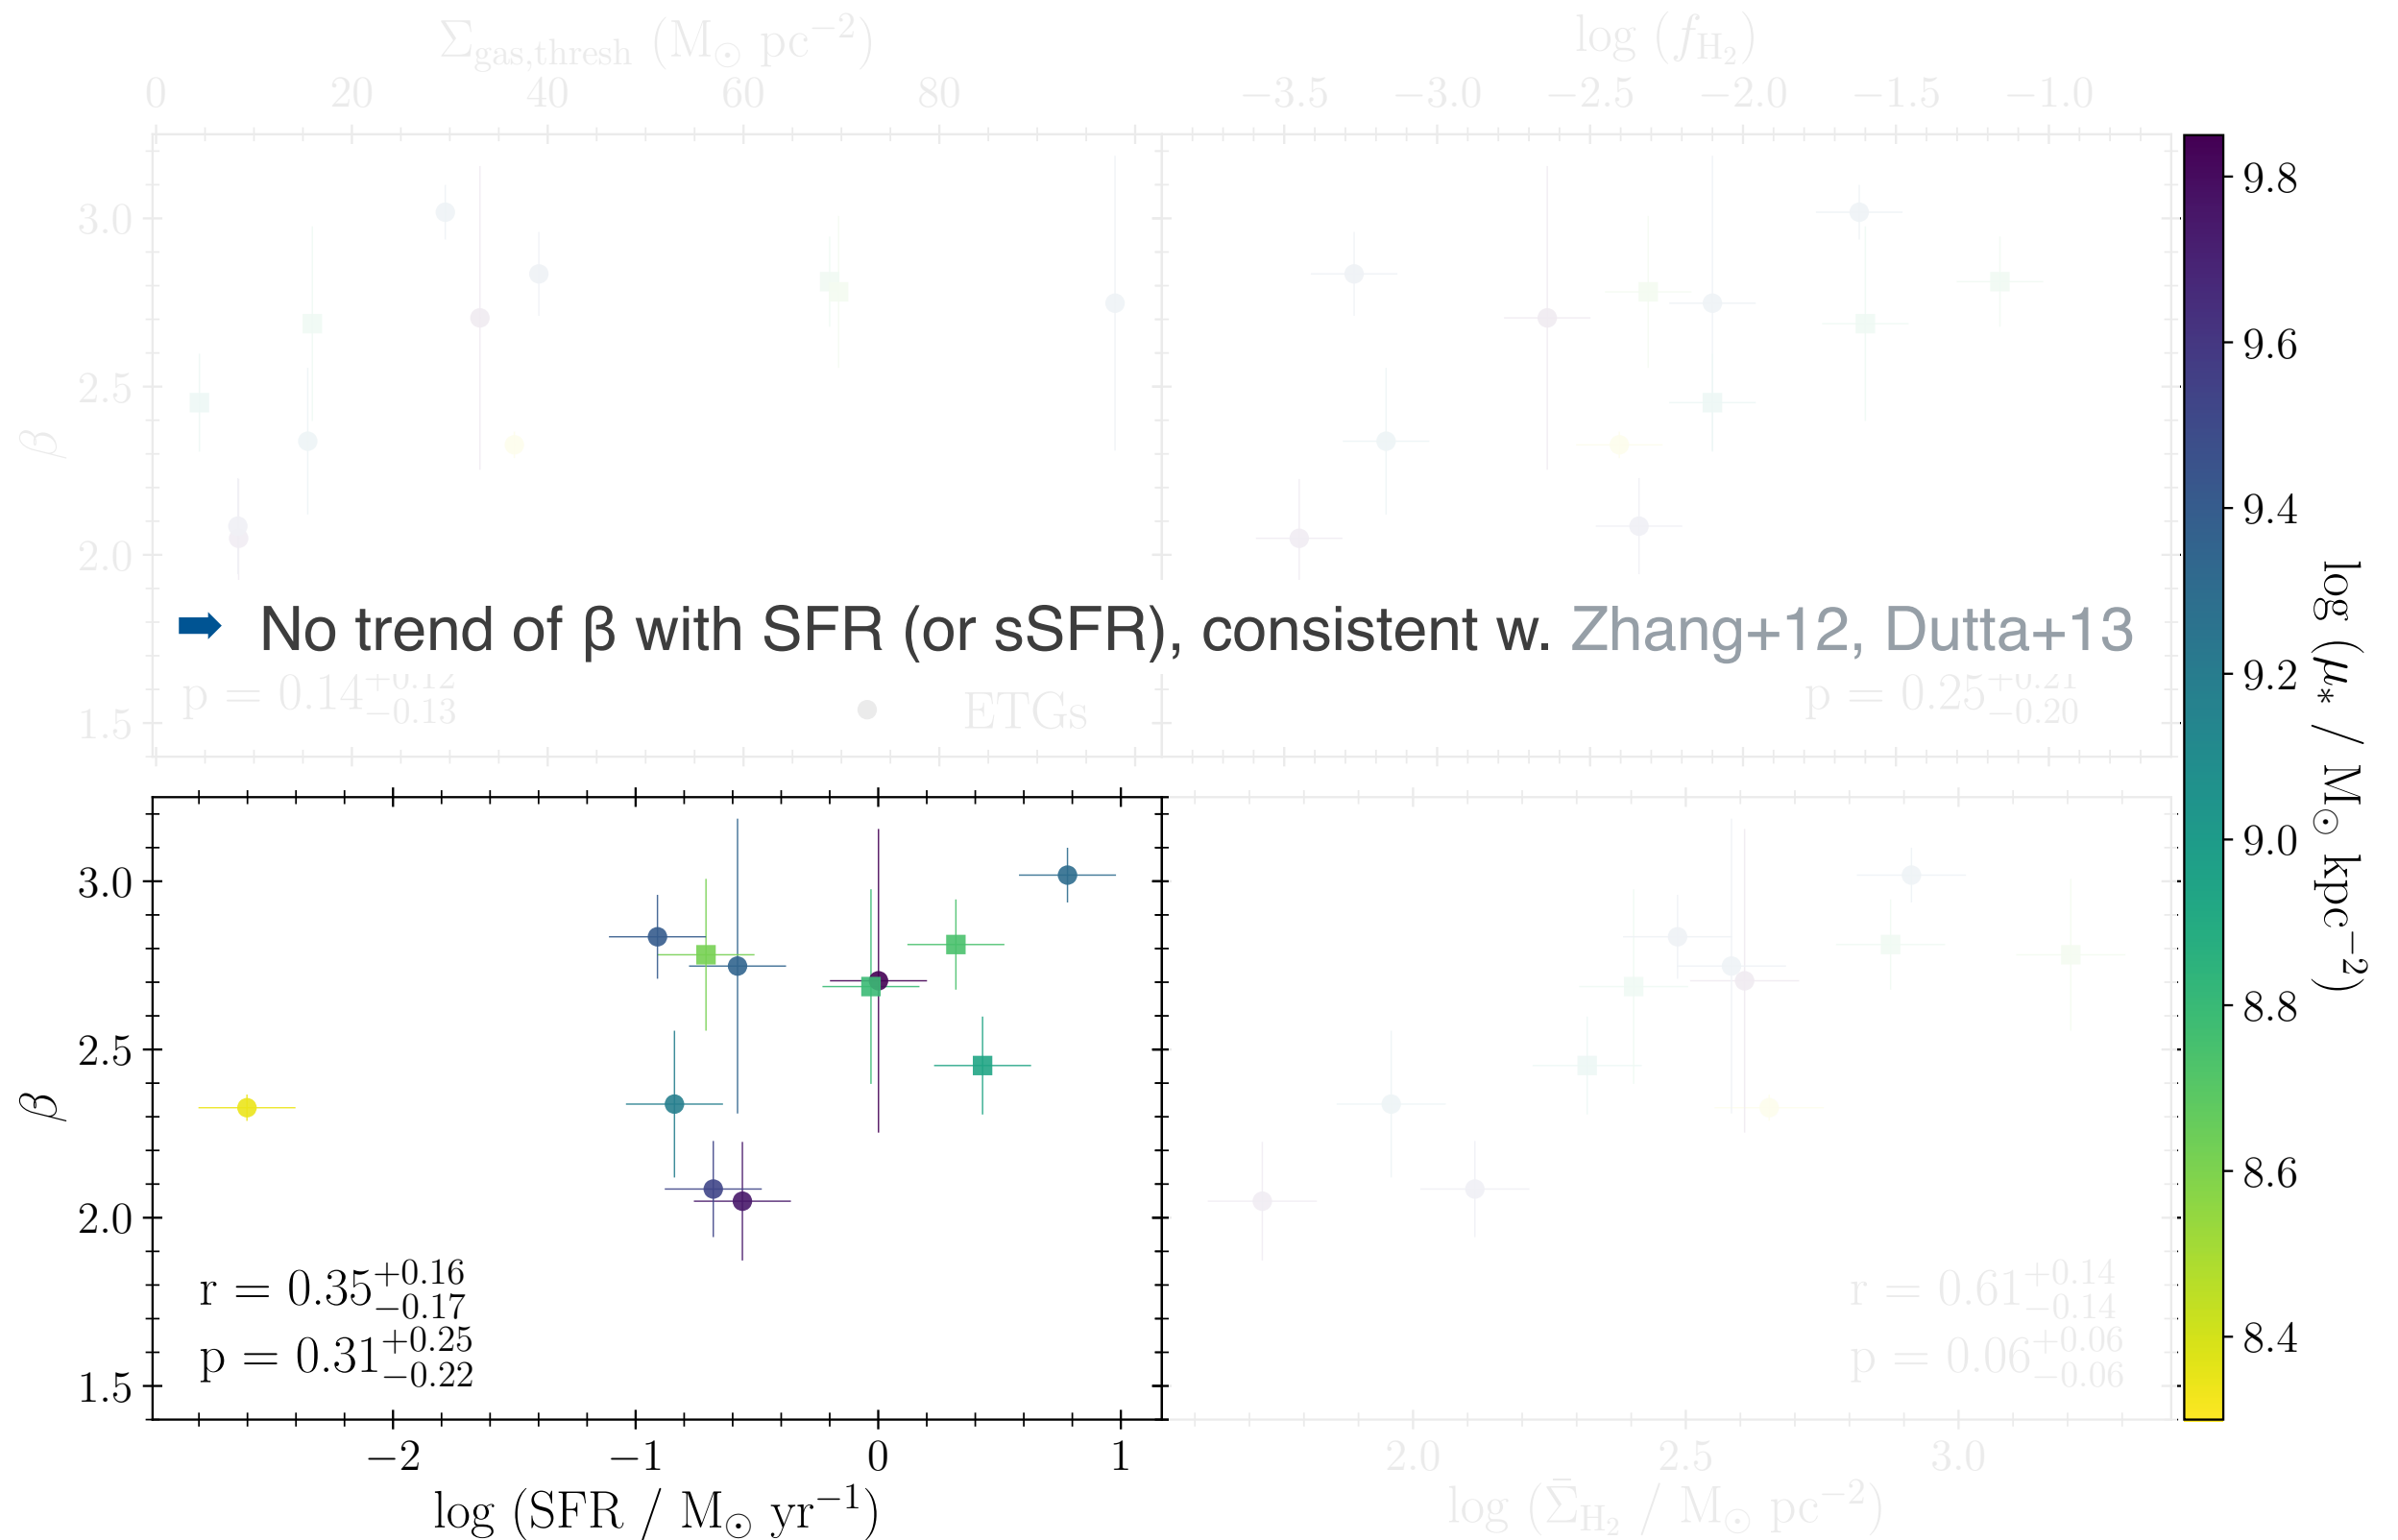

OBSERVATIONS:

POWER SPECTRUM SLOPE CORRELATES WITH CENTRAL GAS SURFACE DENSITY

OBSERVATIONS:

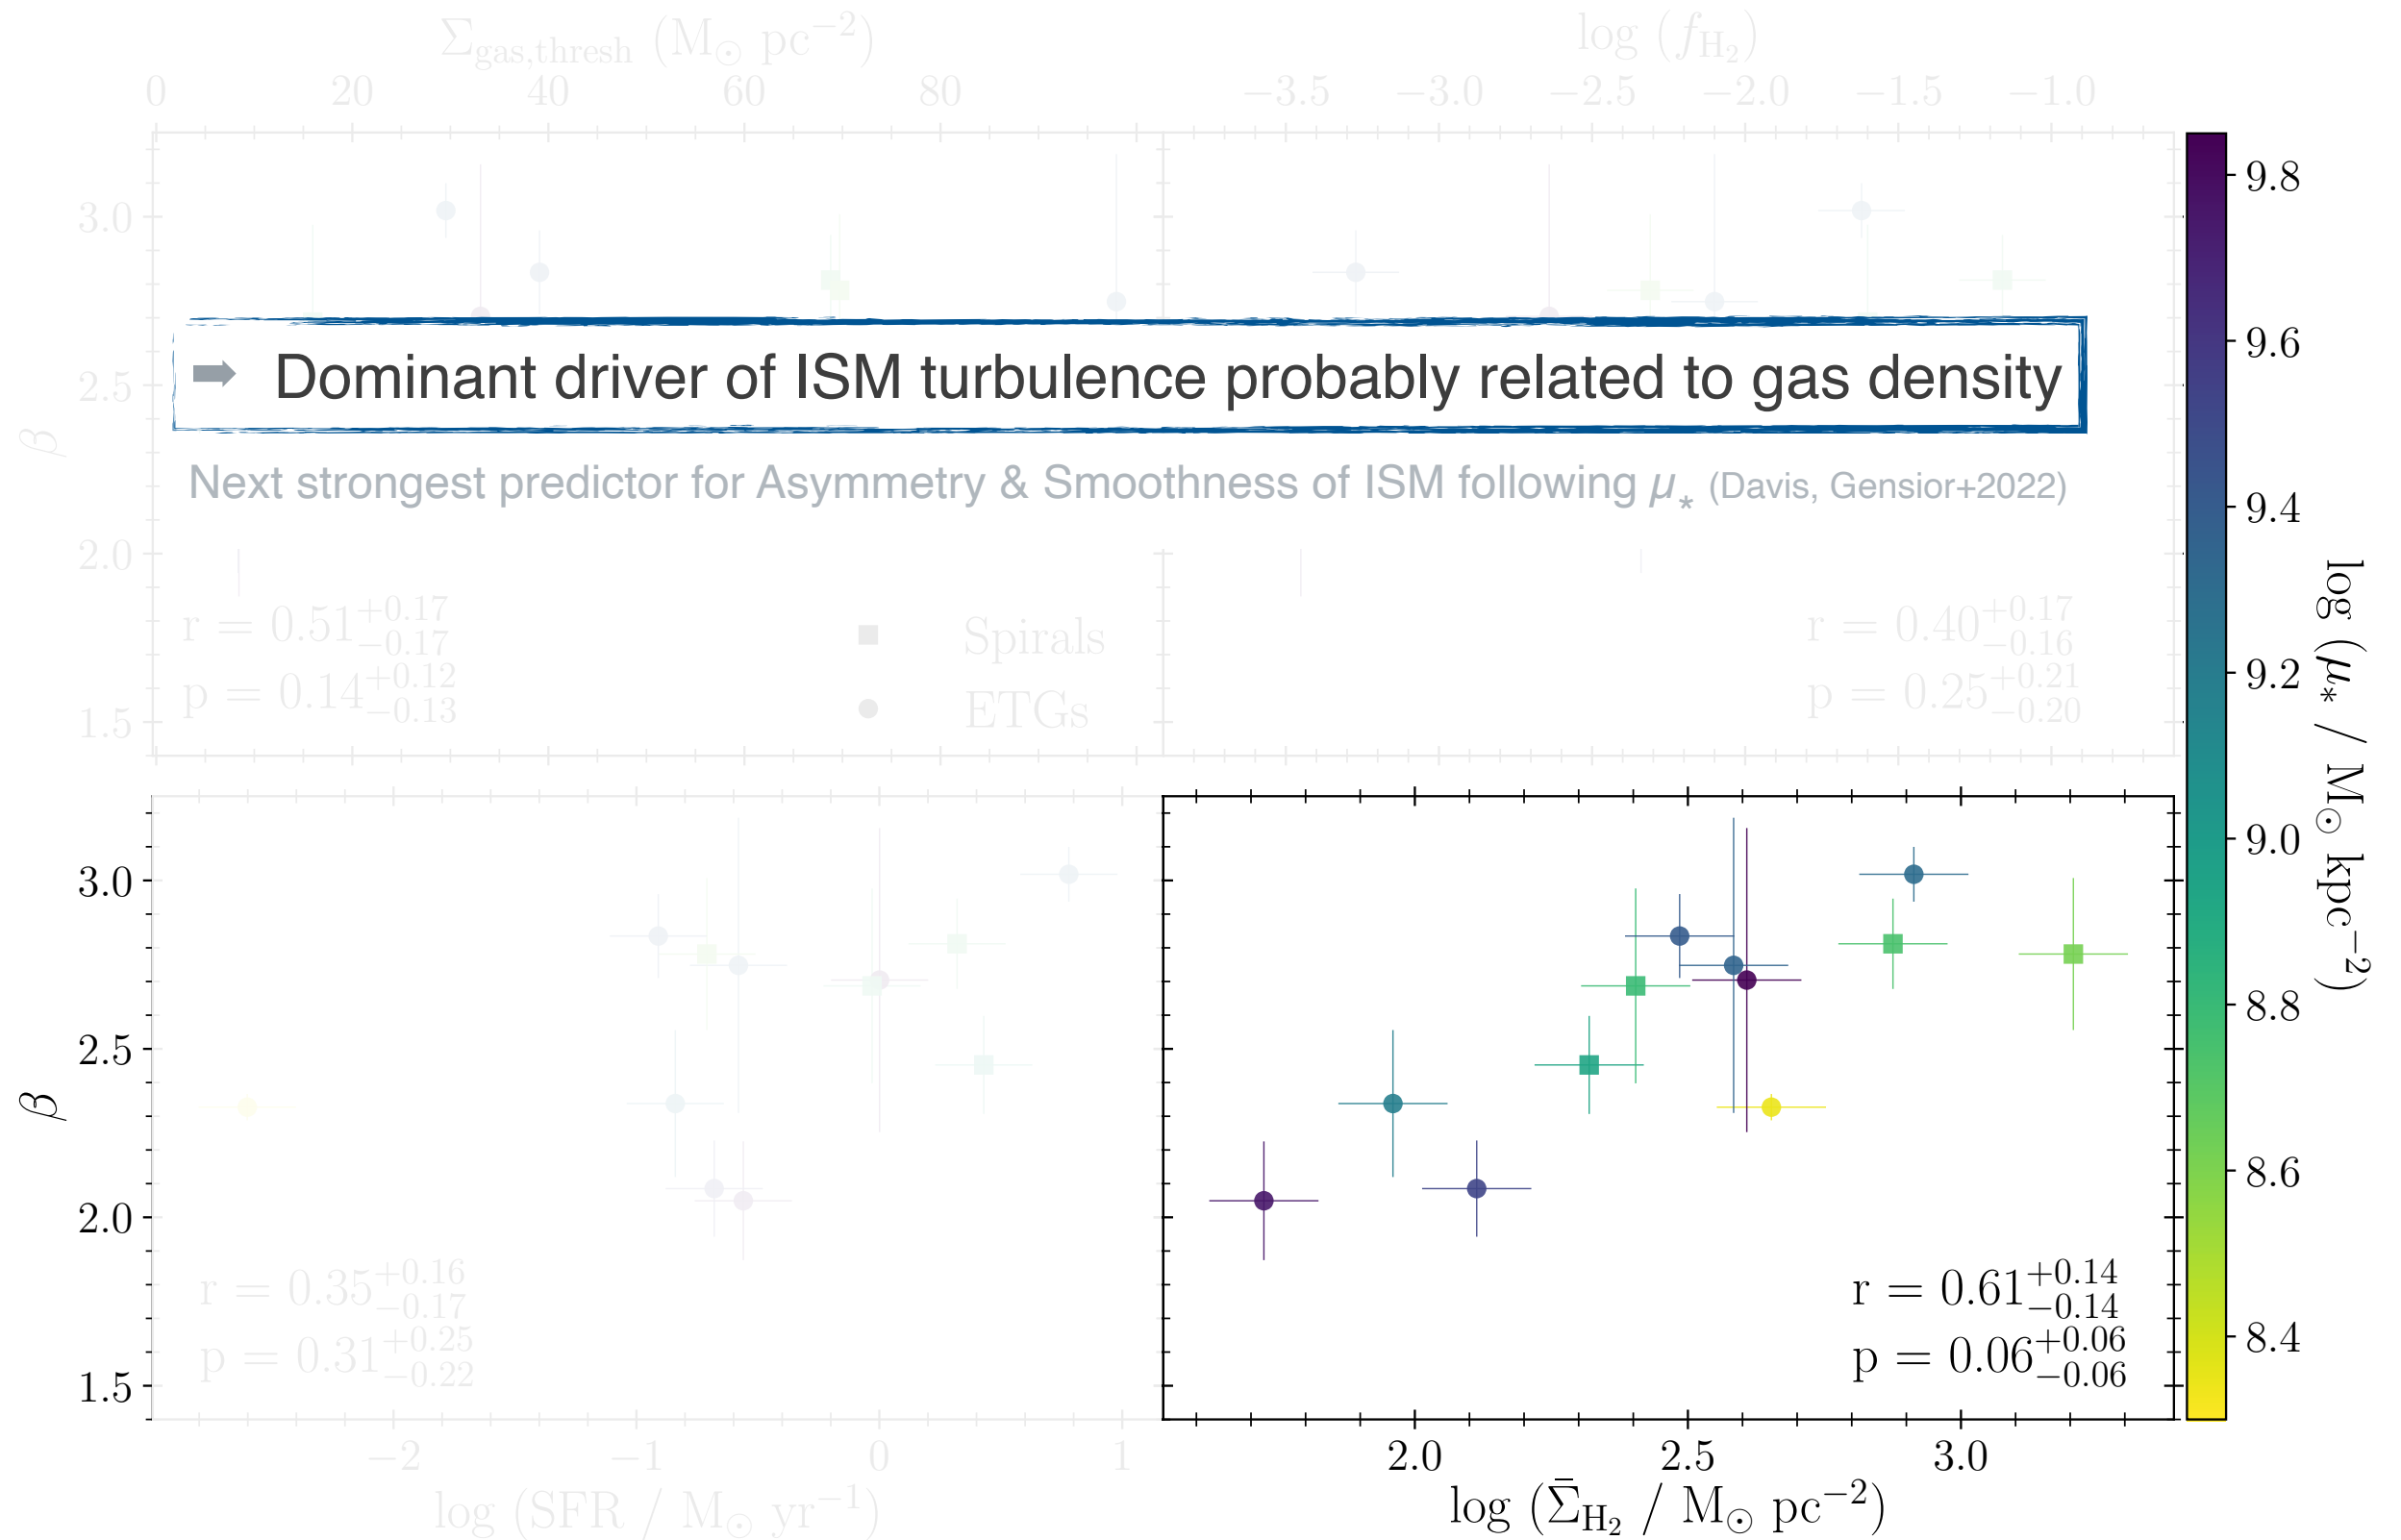

POWER SPECTRUM SLOPE CORRELATES WITH CENTRAL GAS SURFACE DENSITY

➔ No trend of β with SFR (or sSFR), consistent w. Zhang+12, Dutta+13

OBSERVATIONS:

POWER SPECTRUM SLOPE CORRELATES WITH CENTRAL GAS SURFACE DENSITY

SUMMARY

- Galactic gravitational potential and galactic dynamics matter: high shear creates smooth gas discs at the centres of spheroids
- Low Gini, Asymmetry & Smoothness coefficients (**simulations** & **observations**)
- Strong correlation between power spectrum slope (β) and central stellar mass surface density (μ_*) confirms suppression of fragmentation in spheroid-dominated galaxies (**simulations**)
- **Observations** show no correlation between β and μ_*
 - Could indicate that missing physics in the simulations
 - Scatter around $\beta \sim 2.6-2.7$ at high- μ_* , consistent with the slopes of the simulations could indicate shear-driven incompressible turbulence in this regime
 - β correlates with central gas mass surface density
 - ➔ Dominant driver of ISM turbulence probably related to gas density

MULTI-COMPONENT POWER-LAWS
