Classical Image

Pixel values Ci are 32-bit floats Requires 32N^2 bits

SKACH Winter Meeting 22 January 2024 Emma Tolley

Quantum binary encoding: simply map each bit (0 or 1) to a quit (10> or 11>) without using any entanglement or superposition Requires 32N^2 qubits

GUANTUM DATA ENCODING

Quantum lattice: represent each pixel with a single qubit with superposition:

 $|\Psi_k\rangle = \cos \theta_k |0\rangle + \sin \theta_k |1\rangle \qquad \theta_k = \frac{\pi}{2}c_k$

Requires only N^2 qubits, but compression comes at the cost of additional quantum uncertainty

SKACH Winter Meeting 22 January 2024 Emma Tolley

GUANTUM DATA ENCODING

Flexible Representation of Quantum Images (FRQI): encode positional information with with entangled qubits:

$$|\Psi\rangle = \frac{1}{2^n} \sum_{k=0}^{N^2 - 1} (\cos \theta_k |0\rangle + \sin \theta_k |1\rangle) \otimes |k\rangle$$

Requires only log(N^2)+1 qubits

Emma Tolley SKACH Winter Meeting 22 January 2024

Represent pixel coordinates as binary strings, for example: $|k = 2\rangle = |0\rangle \otimes ... \otimes |1\rangle \otimes |0\rangle$

QUANTUM DATA ENCODING

Quantum Probability Image Encoding (**QPIE**): encode positional information with with entangled qubits:

$$|\Psi\rangle = \sum_{k=0}^{N^2 - 1} c_k |k\rangle$$

Requires only log(N^2) qubits!!

Represent pixel coordinates as binary strings, for example: $|k = 2\rangle = |0\rangle \otimes ... \otimes |1\rangle \otimes |0\rangle$

80

GUANTUM DATA ENCODING

Quantum advantage is directly related to this compression factor in quantum computing. Classical computing Fourier transform on N² pixels: O(N⁴) or O(N² log (N²)) for FFT

Quantum computing Fourier transform (QFT):

- N² pixels represented by log(N²) qubits

However...

Emma Tolley SKACH Winter Meeting 22 January 2024

QFT requires circuit with O($\log(N^2)$) $\log(N^2)$) gates => exponential algorithmic speedup

SOURCE RECONSTRUCTION ACCURACY

SNR=10

Optimal QPIE circuit depth: $O(f(N^2)) = O(\log_2 N \times \log_2 N)$ Complexity of QFT is: $O(\log_2 N \times \log_2 N)$

Total complexity is:

However...

- $O(N_{\text{shots}} \times \log_2 N \times \log_2 N)$
- For SNR=10 source reconstruction: $N_{\text{shots}} = O(N^2)$ **Beats classical** O(N⁴) **FT but not** O(N² log (N²)) **FFT**
- For SNR=100 source reconstruction: $N_{\text{shots}} = O(N)$ **Exponential speedup over FFT!**

Real quantum computers are quite noisy, gates and circuits can be corrupted Assuming a uniform gate error rate of: $\epsilon = P(\text{gate fails})$

Then a circuit with depth D will have a global failure rate of: P(at least 1 gate fails) = 1 - P(all gates succeed) $= 1 - (1 - \epsilon)^{D_{\text{circ}}}$

Thus ϵ or D need to be quite small...

Emma Tolley SKACH Winter Meeting 22 January 2024

QUANTUM ERROR

Can measure ϵ and D on the publicly available IBM quantum computers

- ϵ is gate and hardware-dependent, but typical values on current hardware are 10⁻² - 10⁻⁵
- Using a recursive initialization algorithm from Shende et al. (2006) to build the QPIE initialization circuit
- 4x4 image initialized with 74 gates: ~15% failure rate
- 256x256 image initialized with > 20,000 gates: ~100% failure rate

Lower ϵ :

- Rapid developments in the field of quantum hardware, which may improve the quantum error situation
- Quantum error correction can flag corrupted circuits

Lower *D*:

- QRAM: Store data instead of re-encoding it each time
- Improved algorithms for data encoding (interesting proposal in Zhang et al (2021) for encoding a 1024×1024 image with ~ 100 gates)
- Can decompose image to run more, smaller circuits

FUTURE DIRECTIONS

- field of QC
- Quantum FFT? Quantum gridding/degridding? Quantum NU-FFT? Quantum deconvolution?
- Similar study for time-domain/pulsar searches?
- Quantum variational circuits & quantum machine learning

• Quantum error: should be mitigated by continuous developments in the

• Quantum uncertainty: can only be mitigated by algorithmic developments
